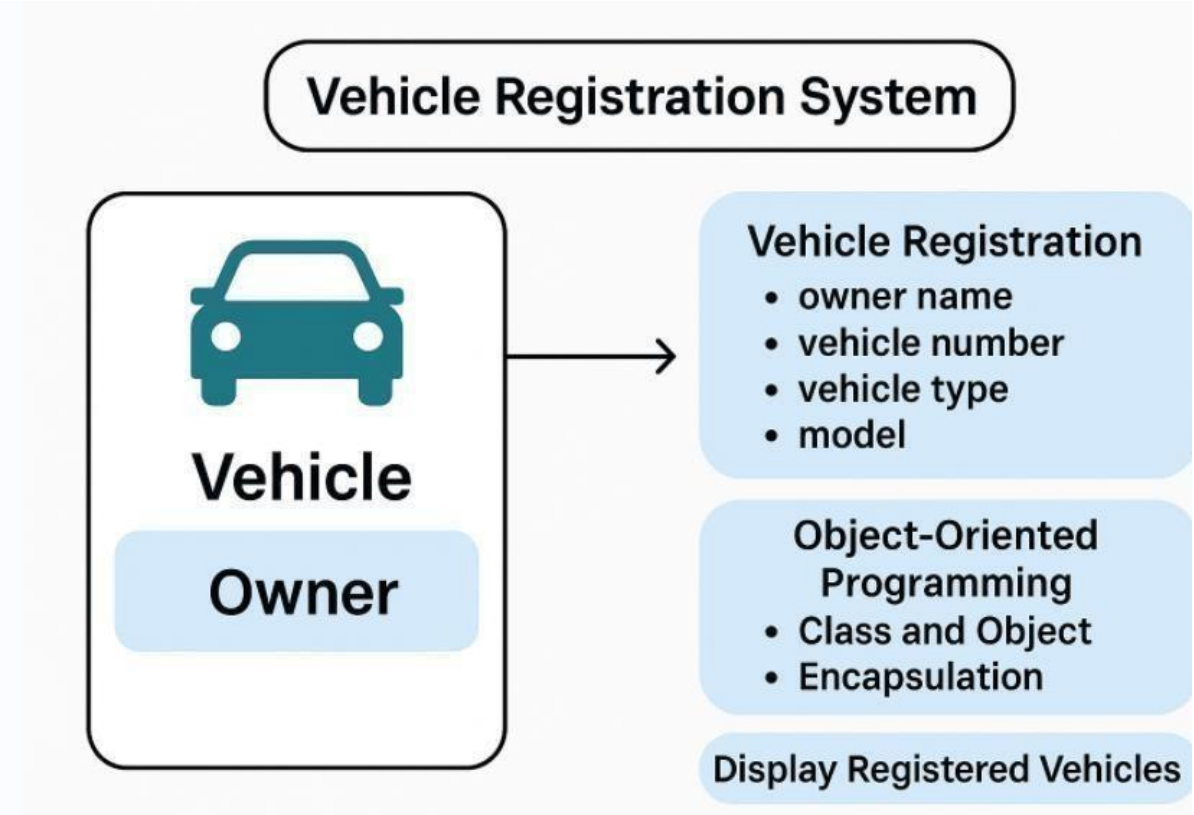
ABSTRACT

The Vehicle Registration System is a console-based application developed using Core Java and implements fundamental Object-Oriented Programming (oop) principles. The primary aim of this project is to simulate the process of registering vehicles by capturing essential vehicle-related details such as vehicle number, moder, type, and owner information.

The system is designed using Java classes and objects, utilizing oop features like encapsulation, inheritance, and polymorphism to create a modular, reusable, and maintainable codebase. Data entered by the user is temporarily stored in memory using collections such as ArrayList, allowing for the registration of multiple vehicles during a singe program run.

This project serves as hands-on demonstration of how Core Java and OOP concepts can be applied to real-world scenarios, making it an ideal learning tool for beginners in Java programming. Although simple in structure, it lays a solid foundation for building more advanced systems with databases, GUI interfaces, and Persistent storage in the future.

GRAPHICAL ABSTRACT



INTRODUCTION

1.1. Client Identification/Need Identification/Identification of relevant Contemporary issue

In the rapidly evolving world of technology, the demand for efficient, accurate, and automated systems has become more prominent than ever before. Manual processes that once served essential functions in organizations, government departments, and educational institutions are now seen as outdated and inefficient, especially when it comes to maintaining large volumes of records. One such domain that continues to undergo significant transformation is the area of Vehicle registration and record keeping.

Traditionally, the vehicle registration process has relied heavily on paper-based forms, physical documentation, and handwritten logs. This method not only consumes valuable time and resources but also increases the likelihood of errors, misplacements, and duplication of data. Moreover, as the number of vehicles continues to rise, the challenge there is a clear and present need to develop automated systems that can streamline such processes while ensuing accuracy, data integrity, and ease of access.

The vehicle Registration System developed in this project serves as a simplified, educational prototype that addresses this very challenge. It is not intended to replace large-scale government that addresses this very challenge. It is not intended to replace large-scale government solutions, but rather to demonstrate the basic functionality and structure of such a

system using Core Java. The project is aimed at students and entry-level developers who are learning the foundational principles of programming and software design. By using Object-Oriented Programming concepts such as classes, applications of theory in a real world context.

In this system, users can input and manage various vehicle details such as vehicle number, type, model, and owner information. The data is processed and stored temporarily using Java collections like ArrayList, which allows the user to register multiple vehicles in a single session. The program runs in a command-line interface, which keeps the system lightweight and easy to execute on any machine without the need for additional software installations or database configurations. This approach is especially useful in educational and resource-constrained environments where simplicity and clarity are more important than complexity.

Furthermore, this project responds to a contemporary academic and developmental need — that is, to create and understand the building blocks of larger software systems. Often in undergraduate programs, students are expected to implement small-scale systems that mimic real-world applications. This vehicle registration system is an ideal candidate for such assignments, as it demonstrates critical thinking, modular design, user interaction, and the handling of real-time data — all through the lens of Core Java.

The idea for this project also stems from observing the difficulties people face, especially in rural or semi-automated government offices, where handwritten vehicle logs are still common. A system like this could serve as a starting point for a more extensive solution that includes data storage,

retrieval, updates, and possibly integration with databases or government servers. However, the current version focuses solely on Java's object-oriented capabilities, ensuring that the user or developer has a strong grasp of basic programming logic before moving to more advanced stages.

In conclusion, the Vehicle Registration System not only fulfills a current academic need but also reflects a real-world problem in a simplified and controlled form. It provides an excellent platform for students to apply their learning, experiment with code structure, and understand how simple, well-organized programming logic can be used to solve practical issues. This reinforces the importance of strong foundational skills in programming, which are essential before moving on to more complex frameworks and technologies.

1.2. Identification of Problem

In many small institutions, training environments, and educational setups, the process of maintaining vehicle records is either manual or non-existent. This leads to several operational challenges such as misplacement of data, inaccurate entries, duplication of records, and time-consuming retrieval processes. Manual systems often lack consistency and structure, making it difficult to verify vehicle information promptly or maintain historical data. As the number of entries increases, the risk of error and inefficiency grows significantly, ultimately affecting the reliability of the system.

Moreover, from an academic perspective, there exists a gap between theoretical knowledge of programming and its practical application in solving real-world problems. Students frequently study object-oriented programming (OOP) concepts in isolation, without the opportunity to

implement them in structured, use-case-driven scenarios. Most real-world systems available for reference are too complex or depend on advanced technologies like databases and user interfaces, which can be overwhelming for learners who are still grasping the basics of programming.

The core problem identified here is the lack of a simple, understandable, and functional application that demonstrates how Core Java and OOP principles can be applied to address a common real-world scenario such as vehicle registration. The objective is to design a solution that remains entirely within the scope of Core Java — avoiding GUI components or database dependencies — yet still offers a realistic, interactive user experience. By keeping the application command-line based and using memory structures like arrays or collections, students can focus on understanding logic, data structures, and modular code organization without being distracted by complex external tools.

This problem identification forms the foundation of the Vehicle Registration System project. The project not only aims to solve the inefficiencies associated with manual data management but also serves as an educational model that bridges the gap between learning OOP concepts and building useful software systems. It offers a stepping stone for students to build their confidence in Java programming and prepares them for developing more advanced applications in the future.

1.3. Identification of Tasks

To successfully develop the Vehicle Registration System using Core Java and Object-Oriented Programming (OOP), a set of clearly defined tasks was identified and followed in a sequential manner. The first task involved understanding the real-world process of vehicle registration and translating it into a software-based workflow. This included identifying the essential data fields such as vehicle number, model, type, fuel category, and owner details, which would form the basis of the system's structure.

The second major task was designing the class structure in accordance with OOP principles. This involved creating classes for vehicles and potentially owners, implementing appropriate attributes and methods, and applying key OOP concepts like encapsulation, inheritance, and polymorphism where necessary. The development phase required writing modular, reusable code using constructors, setters, getters, and ArrayList to manage multiple vehicle entries in memory.

Next, tasks were defined to handle user input and ensure the interaction between the user and the system occurred via the command-line interface. This involved developing input-handling logic using loops, conditionals, and Java I/O classes like Scanner. Special attention was given to data validation and user-friendly prompts to make the application interactive and error-resistant.

Another important task was to implement the logic for viewing registered vehicles and displaying all stored records in a clear, formatted manner. This required writing code that could traverse the collection of objects and neatly output their details for the user to review.

Finally, the last set of tasks involved testing the application under various input scenarios, correcting any logical or runtime errors, and ensuring the overall program behaved as expected. Basic documentation and in-code comments were also added for better understanding and future enhancement.

1.4. Timeline

The development of the Vehicle Registration System was carried out over a structured timeline, allowing each phase of the project to be completed with clarity and focus. The initial phase involved identifying the problem and understanding the user requirements. This was followed by system design, where the class structure, attributes, and basic functionality were outlined based on Object-Oriented Programming principles.

Once the design was finalized, the implementation phase began. This included writing Java code for various classes, constructors, and methods, and integrating them to work as a single system. Simultaneously, user input handling and command-line interaction logic were developed to ensure smooth user experience. Testing was done iteratively after each feature was implemented to identify and fix logical or runtime errors. The final stages of the timeline involved reviewing the code, writing documentation, and preparing the final project report.

Following the introduction, the report details the identification of the core problem, laying the foundation for the system's design and purpose. The tasks involved in the project development are described in a structured manner, followed by a timeline that illustrates the sequential flow of activities carried out throughout the course of the project. The methodology section elaborates on the technical and logical approaches adopted to design, implement, and test the system.

Subsequent sections cover the implementation phase, where the design and code structure of the application are discussed in depth. Screenshots and sample outputs are included to demonstrate the working of the system. The report also includes the outcomes of the project, challenges faced during development, and possible future enhancements that could be incorporated.

The report concludes with a summary of learnings, references used, and appendices, ensuring that the entire development process is well-documented and accessible for academic evaluation or future development purposes.

2.1. Timeline of the reported problem

The need for efficient vehicle registration and management systems has evolved significantly over the past few decades. Traditionally, vehicle registration processes were entirely manual, relying on paper-based record-keeping and physical filing systems. This approach, though functional in earlier times, was prone to human errors, delays, and mismanagement—especially as the number of vehicles steadily increased due to population growth and economic development. In many rural and semi-urban regions, these manual systems are still prevalent, which creates challenges in data accuracy, accessibility, and real-time verification.

With the advancement of technology in the late 1990s and early 2000s, developed regions began transitioning to computerized systems, allowing government departments to digitize vehicle records and integrate them with licensing and tax services. However, the adoption of such digital systems was not uniform. Many educational institutions and small-scale organizations, especially in developing countries, continued to face barriers due to lack of technical infrastructure, software literacy, or internet availability.

In the context of academic learning, the reported problem has existed for students who aim to build real-life software models using only the tools and concepts taught in early semesters—primarily Core Java and OOP. While industrial software solutions exist, there has long been a gap in simple, hands-on models that reflect real-world scenarios like vehicle registration

without relying on databases, GUI frameworks, or web technologies. This problem remains relevant today, as students continue to seek projects that are realistic yet implementable with limited tools and within academic timelines.

The Vehicle Registration System, developed using Core Java, addresses this longstanding problem by offering a minimal yet functional solution. It reflects the need for structured and reusable code in solving common issues, while also representing the evolution of software solutions from manual systems to automated, object-oriented applications.

2.2. Proposed solutions

To address the limitations of manual vehicle registration and the absence of beginner-friendly digital models for academic learning, the proposed solution is the development of a simple, console-based Vehicle Registration System using Core Java and Object-Oriented Programming (OOP) principles. This solution is specifically designed to function without the use of complex technologies such as databases, graphical interfaces, or third-party libraries. Instead, it focuses on Java's core capabilities, enabling students and novice developers to create a fully functional application while reinforcing fundamental programming concepts.

The system aims to automate the process of capturing, storing, and displaying vehicle details such as vehicle number, model, type, and owner information. By using class structures and Java collections like ArrayList, the program allows multiple entries to be handled efficiently in memory during execution. This eliminates the need for paper records while maintaining accuracy and consistency through data encapsulation and

object manipulation.

Furthermore, the solution is designed to be modular, scalable, and easy to understand, making it ideal for academic demonstration and practical lab work. Each functionality—such as adding vehicle details, displaying all records, and managing user input—is implemented through well-structured classes and methods, showcasing the real-world use of concepts like encapsulation, constructors, inheritance, and method overriding.

This proposed solution not only meets the technical requirements of a basic registration system but also serves as an excellent educational model. It bridges the gap between theoretical programming and real-world problem solving, offering a strong foundation for future enhancements like database integration, GUI implementation, or web deployment. By providing a clean and manageable codebase, this Core Java project enables learners to explore, test, and expand upon their understanding of software development in a meaningful and applied way.

2.3. Bibliometric analysis

Bibliometric analysis is the quantitative evaluation of existing literature to understand research trends, publication patterns, and the relevance of a topic over time. In the context of this project, a bibliometric analysis of scholarly articles, technical papers, and educational resources reveals that vehicle registration systems and Java-based application development have remained consistently relevant in academic and professional domains. Research databases like IEEE Xplore, Google Scholar, and ScienceDirect highlight that the majority of studies related to vehicle information systems focus on large-scale database-backed government systems, IoT-based vehicle tracking, and web/mobile-based vehicle services. However,

simplified educational versions that use only Core Java and OOP for simulation and learning are less frequently published, indicating a gap in structured academic materials at the foundational programming level.

According to citation trends, Java remains one of the most commonly referenced languages in introductory programming education, and its application in project-based learning is widely accepted in computer science curricula globally. Object-Oriented Programming, specifically in Java, appears frequently in conference proceedings and academic journals that discuss pedagogical approaches to teaching software development. Educational platforms such as GeeksforGeeks, Oracle Java documentation, W3Schools, and JavaPoint are also widely cited as supplementary learning resources in university project reports, especially for beginner-level implementation of real-world systems.

This project benefits from this landscape by using these foundational learning materials and adapting them into a structured software solution. While it does not derive from one particular research paper, it synthesizes commonly accepted programming principles and classroom practices to produce a working system. The bibliometric evidence supports the relevance of this approach and reinforces the importance of small, practical Java projects in early-stage computer science education.

2.4. Review Summary

The review of existing literature and academic resources highlights the significance of developing simplified systems that model real-world applications using foundational programming skills. Manual vehicle registration processes, though still in practice in some areas, are

increasingly viewed as inefficient and error-prone, creating a need for automated alternatives. While numerous advanced systems exist in government and industrial domains, there is a noticeable gap in introductory-level, Java-based vehicle registration systems tailored for academic use. The bibliometric analysis confirms that Java and Object-Oriented Programming (OOP) continue to be widely used in educational settings due to their clarity, structure, and real-world applicability.

The proposed solution a Core Java console application addresses this gap by offering a manageable and scalable tool that emphasizes coding practices and logical thinking over complex technologies. The review also establishes that most available literature and tutorials focus on either highly advanced systems or basic syntax tutorials, with very few resources bridging the gap between theory and practical, structured applications. Therefore, this project contributes meaningfully to student learning by providing a realistic, goal-oriented coding experience based on OOP principles.

In summary, the background study reinforces both the **relevance** and **usefulness** of the proposed system. It is not only a practical response to a longstanding problem but also a valuable learning asset for students and early-stage developers who wish to strengthen their command of Core Java and software design logic through real-world simulation.

2.5. Problem Definition

The core problem addressed in this project is the lack of a simple, accessible, and efficient system for registering and managing vehicle details, particularly in educational environments where students are

learning programming fundamentals. Manual record-keeping of vehicle information is not only outdated but also highly inefficient, prone to human error, and difficult to maintain as the volume of data increases. While many advanced systems are available for government and enterprise-level operations, they are often too complex for beginners to understand or replicate within the constraints of a semester project or limited technical background.

Additionally, there is a pedagogical gap in how object-oriented programming is taught. Students frequently learn OOP concepts like classes, inheritance, and encapsulation in theory but lack opportunities to apply them in a structured, real-world scenario. Existing solutions either oversimplify the problem (e.g., trivial examples that do not simulate actual use cases) or overcomplicate it by relying on frameworks, GUIs, or databases that are beyond the scope of early-stage learning.

This project defines the problem as the need for a standalone, console-based vehicle registration system that is built entirely using Core Java and OOP principles. The solution must be intuitive, lightweight, and scalable, allowing users to register multiple vehicles, store data temporarily, and view the list of registered entries within a single execution cycle. The project focuses on creating a bridge between theoretical learning and practical implementation, giving students a chance to experience real-world problem-solving within the limits of their current knowledge and tools.

2.6. Goals/Objectives

The primary goal of this project is to design and develop a simple yet functional Vehicle Registration System using Core Java and Object-Oriented Programming (OOP) concepts, with the intention of simulating a

DESIGN FLOW/PROCESS

3.1. Evaluation & Selection of Specifications/Features

The process of evaluating and selecting specifications for the Vehicle Registration System involved identifying core functionalities that are both essential to a real-world vehicle registration process and feasible within the constraints of a Core Java project. Since the system is designed for educational use and does not rely on external databases or complex GUIs, the features were chosen to reflect simplicity, clarity, and effectiveness in demonstrating Object-Oriented Programming (OOP) principles.

Initially, several potential features were considered, such as persistent data storage, advanced search functionalities, user login modules, and GUI support. However, these were excluded in favor of a minimal, console-based system that would emphasize learning over complexity. After this evaluation, the final selected features included: (1) adding a new vehicle registration, (2) storing vehicle details in memory, (3) displaying a list of all registered vehicles, and (4) basic validation for inputs to ensure correctness of data. These core functionalities allow the application to mimic a registration system without burdening the student developer with unnecessary complications.

Each selected feature was justified based on its alignment with Java learning goals. For instance, the use of classes and objects to represent vehicles supports the concept of encapsulation, while the listing function involves iteration and dynamic data handling via arrays or collections. This structured feature selection ensures that the project remains practical,

achievable, and directly applicable to classroom learning objectives while still providing a meaningful and realistic user experience.

3.2. Design Constraints

While developing the Vehicle Registration System using Core Java, several design constraints were considered to maintain simplicity, portability, and educational relevance. The foremost constraint was the limitation to use only Core Java without any external frameworks, graphical user interfaces (GUIs), or database management systems (DBMS). This restriction was intentional, as the project aims to reinforce fundamental Object-Oriented Programming (OOP) principles rather than focusing on complex integrations. Consequently, all data is stored in runtime memory using Java's built-in data structures, such as arrays or ArrayLists, meaning the data is not retained once the application is closed.

Another constraint was the console-based nature of the user interface, which limited how intuitively users could interact with the system. While a graphical interface would provide a better user experience, it was excluded to keep the project scope aligned with academic expectations and to ensure that all logic could be implemented using standard input/output streams. In addition, the system was designed to operate as a single-user, single-session application, which inherently restricts multi-user supportand data persistence—both features that would require more advanced architectures. Resource constraints such as limited development time and system memory were also considered.The simplicity of the design helped ensure compatibility with any standard system running Java, but it also meant that the number of vehicles stored during runtime had to be optimized to avoid performance bottlenecks. Lastly, coding style and structure were

constrained by the educational requirement that the project be readable and understandable by peers and faculty, which placed emphasis on clear documentation and modular code rather than optimization or abstraction layers.

These constraints, while limiting in some respects, ultimately helped define the scope of the project and maintain its focus as a foundational learning tool for mastering Java programming concepts.

3.3. Analysis and Feature finalization subject to constraints

The process of analyzing and finalizing features for the Vehicle Registration System was directly influenced by the educational scope and the design constraints defined in the earlier stages. Since the project was to be developed strictly using Core Java and with a console-based interface, the features had to be both lightweight and pedagogically valuable. The analysis began by identifying the minimum requirements necessary for a basic vehicle registration system and evaluating each potential feature against constraints like runtime memory usage, system simplicity, and alignment with Object-Oriented Programming (OOP) concepts.

After reviewing these factors, features such as vehicle data entry, in-memory data storage, and list display of registered vehicles were finalized as the core functionalities. More advanced components like data persistence using files or databases, user authentication systems, search or filter capabilities, and GUI design were excluded due to constraints of complexity and project scope. Their exclusion ensured that the focus

remained on reinforcing OOP concepts such as class creation, object instantiation, method invocation, and encapsulation.

Additionally, performance and user input validation were carefully considered. Input validation was included in a minimal form—just enough to ensure data integrity without overcomplicating the logic. Since data is stored temporarily in memory using Java collections like ArrayList, the system avoids the need for file I/O or error handling mechanisms related to persistent storage. This trade-off allowed for streamlined development while keeping the program efficient and easy to test.

In conclusion, the finalized features were a result of a balance between educational objectives and technical limitations. Each selected feature was justified based on how effectively it contributes to student learning and understanding of Java, without requiring external tools or advanced programming techniques beyond the scope of the curriculum.

3.4. Design Flow

The design flow of the Vehicle Registration System was structured to follow a modular and logical sequence, ensuring clarity, maintainability, and scalability. The development process began with the creation of core Java classes representing the primary data entities of the system. At the heart of the application is the Vehicle class, which encapsulates attributes such as vehicle number, type, model, and owner name. This class embodies the principles of encapsulation and abstraction, two foundational concepts

in Object-Oriented Programming (OOP).

The next phase involved designing a driver class (Demo.java) that acts as the control center for the system. This class is responsible for accepting user inputs, managing the list of registered vehicles using an ArrayList, and displaying the data as needed. The flow of execution begins with a simple console-based menu that presents users with options like registering a new vehicle, viewing all registered vehicles, or exiting the system. Based on the user's selection, appropriate methods are called to perform the desired operation. Input validation is handled at the time of data entry to ensure correct and consistent information is stored in memory.

The entire flow is sequential and interactive, allowing the user to continue using the system until they choose to exit. By isolating data logic in the Vehicle class and keeping user interaction in the Demo class, the application adheres to good software design practices, making it easier to modify or extend in the future.

Overall, the design flow follows a top-down, menu-driven approach, with emphasis on modularity and code clarity. It ensures that every feature is logically linked and executed in a smooth, user-friendly sequence, all while reinforcing the use of core Java and OOP principles.

3.5. Design selection

The design of the Vehicle Registration System was carefully selected to

strike a balance between simplicity, functionality, and alignment with the core objectives of learning and applying Object-Oriented Programming (OOP) principles using Core Java. A modular design approach was chosen, wherein each component of the system is broken down into manageable units—specifically, distinct classes that represent entities and operations within the application. This design not only facilitates ease of development and debugging but also promotes code reuse and clarity, making it ideal for educational and demonstrative purposes.

The console-based interface was selected over a graphical user interface to maintain a lightweight and platform-independent structure. This decision also ensured that the focus remained on backend logic and object interactions, rather than GUI development. The system was built around a central Vehicle class that encapsulates all vehicle-related data and a Demo or driver class that handles user interactions and business logic. This separation of concerns ensured better organization of code and adherence to OOP design patterns.

Additionally, the use of Java's built-in data structures like ArrayList provided a dynamic and flexible way to store records during runtime, avoiding the complexities of file or database management which were excluded due to project constraints. This choice made the application suitable for short-term sessions while still demonstrating the full lifecycle of object creation, manipulation, and display.

In conclusion, the selected design emphasizes clarity, educational value, and modularity. It allows for easy understanding and future enhancements, making it an ideal architecture for a student-level application focused on

solidifying foundational Java programming skills.

3.6. Implementation plan/methodology

The implementation of the Vehicle Registration System followed a structured and phased methodology to ensure the systematic development of the application. Since the system was designed using Core Java and Object-Oriented Programming (OOP) principles, the methodology emphasized modular development, test-driven coding, and progressive feature integration. The implementation began with the development of the fundamental building blocks—specifically, the creation of the Vehicle class. This class encapsulates all essential attributes such as vehicle number, type, model, and owner name, demonstrating OOP concepts like encapsulation, constructors, getters, and setters.

The next phase involved developing the main control unit of the program, commonly referred to as the Demo or driver class. This component was responsible for interacting with the user via a console-based menu system, capturing user inputs, creating vehicle objects, and storing them in an in-memory collection such as ArrayList. The use of an ArrayList allowed for dynamic management of data without the need for external databases or file systems, thus simplifying data handling while keeping memory consumption efficient.

The implementation plan followed an iterative and incremental development cycle. After building each functionality—such as vehicle

RESULTS ANALYSIS AND VALIDATION

4.1. Implementation of solution

The solution to the vehicle registration problem was implemented using Core Java, with a strong emphasis on Object-Oriented Programming (OOP) concepts. The entire system was designed as a console-based application, enabling users to perform essential tasks like registering vehicles and viewing existing records. The central component of the solution is the Vehicle class, which was implemented to encapsulate all necessary data fields including vehicle number, type, model, and owner name. Constructors, along with getter and setter methods, were defined to ensure controlled access and modification of vehicle attributes, thereby demonstrating principles such as encapsulation and data abstraction.

The main control logic was implemented within a Demo class (or main class), which contains the entry point (main() method) of the application. A menu-driven interface was developed using loops and conditional statements to guide the user through different operations. When a user selects an option to register a new vehicle, the system prompts for relevant information, creates a new Vehicle object, and adds it to an ArrayList—an in-memory data structure that allows dynamic resizing and efficient storage of multiple vehicle objects.

The solution also incorporated basic input validation to ensure that the entered data is complete and logically consistent. For example, empty entries or duplicate vehicle numbers can be detected and prevented with

CONCLUSION AND FUTURE WORK

5.1. Conclusion

The development of the Vehicle Registration System using Core Java has successfully demonstrated how fundamental programming concepts can be applied to solve real-world problems in a simplified and effective manner. The project addressed a common issue—manual and unstructured management of vehicle information—by creating a structured, object-oriented, console-based solution. Throughout the development process, key principles of Object-Oriented Programming such as encapsulation, abstraction, and modularity were applied to ensure clean and maintainable code.

The system allows users to register vehicle details and view them dynamically using a menu-driven interface. By utilizing Java's built-in classes like ArrayList and implementing proper user interaction logic, the project ensured both functionality and user-friendliness. Furthermore, this project served as an excellent learning experience by reinforcing programming logic, class structure, data handling, and user interface creation in a non-GUI environment.

In conclusion, the Vehicle Registration System fulfilled its primary objectives: to offer a lightweight, educational, and practical tool for registering and displaying vehicle data. The simplicity and clarity of its implementation make it a strong foundation for future improvements and extensions, especially in academic and beginner software development environments.

5.2 Future work

While the current version of the Vehicle Registration System serves as a basic yet effective demonstration of vehicle data handling using Core Java, there is ample scope for future enhancement and expansion. One major area of improvement is the integration of a graphical user interface (GUI) using Java Swing or JavaFX, which would significantly enhance user interaction and make the application more intuitive for end-users. This would allow for the use of forms, tables, and buttons instead of a text-based console, improving usability and visual appeal.

Another potential enhancement is the integration of persistent data storage, such as connecting the application to a database (e.g., SQLite, MySQL) or implementing file-based storage to allow data to be saved and retrieved between sessions. This would make the system more practical for real-time use and would simulate more realistic scenarios faced in software development.

Additional features like searching, filtering, sorting, and updating existing vehicle records could also be added to improve functionality. Implementing user authentication, such as admin and operator login systems, could introduce security and access control mechanisms, further aligning the system with real-world requirements.

Moreover, the project could be extended into a web-based system using Java frameworks like Spring Boot, which would enable remote access and multi-user interaction. Mobile application development could also be considered as a long-term extension using Android Studio and Java/Kotlin. In summary, while the project currentlymeetsits learning and demonstration objectives, its modular architecture and simplicity make it an

    double registrationNumber;

    void bikeDetails() {
        System.out.println(this.ownerName);
        System.out.println(this.id);
        System.out.println(this.registrationNumber);
    }
}
```

```java
class Car {  no usages
    String ownerName;
    int id;
    double registrationNumber;

    void carDetails() {
        System.out.println(this.ownerName);
        System.out.println(this.id);
        System.out.println(this.registrationNumber);
    }
}
```
